Research Institute of Innovative Technology for the Earth (RITE)

Contributed by F. Sano, B. Pizer, J. Aldy, M. Tavoni, R. Kopp, and C. Carraro for some estimates
The submitted INDCs include the targets of emissions from different base years, CO2 intensity, and CO2 emission reductions from baseline (w/w.o. clear definition of baseline). We need to interpret them through comparable metrics to measure the efforts:

- **Simple metrics (easily measurable and replicable)**
  - Emissions from the same base year
  - etc.

- **More advanced metrics (more comprehensive, but require forecasts)**
  - Emission reduction ratios from baseline emissions
  - Emissions per unit of GDP
  - etc.

- **Most advanced metrics (most comprehensive, but require modeling)**
  - Energy price impacts
  - Marginal abatement cost (per ton of CO2)
  - Abatement costs as a share of GDP
  - etc.
## Employed indicators for measuring emissions reduction efforts

<table>
<thead>
<tr>
<th>Emissions reduction efforts evaluation method</th>
<th>Framework</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Emissions reduction ratio from base year</strong> (only for OECD countries or Annex I countries)</td>
<td>Compared to 2005</td>
<td>When baseline emissions are expected to stagnate, it is more relevant to simply compare the projected reduction rates (all the more since there are uncertainties regarding the BAU). This is why we use the reduction ratio compared to BAU for OECD countries only - on the other hand, such an approach would be irrelevant for countries where emissions are expected to grow substantially.</td>
</tr>
<tr>
<td>Compared to 2012 (or 2010)</td>
<td></td>
<td>Most countries use 2005 as their base year (as a matter of fact, 1990 seems too far in the past to be used as a base year to evaluate the emissions reduction effort for upcoming emissions) This seems a relatively good choice to evaluate future efforts as it allows assessing reduction ratios in comparison with recent circumstances.</td>
</tr>
<tr>
<td><strong>Emissions per capita</strong> (only for non-OECD countries or non-Annex I countries)</td>
<td>Absolute value</td>
<td>For OECD countries, we adopt the reduction ratio from base year instead of the absolute value of emissions per capita. As it is highly dependent on the country’s level of economic activity and situation in general, it can be difficult to assess emissions reduction efforts through this indicator.</td>
</tr>
<tr>
<td><strong>CO2 intensity (GHG emissions per GDP)</strong></td>
<td>Absolute value</td>
<td>Reveals what level of CO2 emissions corresponds to what degree of economic activity It can easily reach bad values for countries with a low GDP; it is also highly dependent on the country’s industry structure.</td>
</tr>
<tr>
<td>Improvement rate (compared to 2012 or 2010)</td>
<td>As it removes the bias due to the fact that economic growth has changed compared to the base year, it reveals the real effort in emission reduction. For countries with a low GDP, carbon intensity can improve greatly just due to high economic growth.</td>
<td></td>
</tr>
<tr>
<td><strong>Emissions reduction ratio compared to BAU</strong></td>
<td>It allows taking into account the difference of economic growths, etc. It puts aside past efforts in energy savings and abatement potential of renewables.</td>
<td></td>
</tr>
<tr>
<td><strong>CO2 marginal abatement cost (carbon price)</strong></td>
<td>This is a particularly relevant indicator to assess reduction efforts as it contains countries’ differences in terms of economic growth, energy savings efforts, abatement potential of renewables. Past measures such as taxes on energy are out of the scope (however, one must keep in mind that, as energy savings efforts have already been made in the past, this may lead to higher estimates of marginal abatement costs.)</td>
<td></td>
</tr>
<tr>
<td><strong>Retail prices of energy</strong> (electricity, city gas, gasoline, diesel)</td>
<td>Weighted average of historical data from 2012 or 2010</td>
<td>While marginal abatement costs show the additional effort to be made, this indicator also includes the efforts made in the baseline. Market data is available for ex-post evaluation, but for ex-ante evaluation, only model-based estimates are available which makes uncertainties rather high.</td>
</tr>
<tr>
<td><strong>Emission reduction costs per GDP</strong></td>
<td>As marginal abatement costs do not take into account the economy’s ability to bear such an effort, this indicator does. Uncertainties are high as this is a model-based estimation.</td>
<td></td>
</tr>
</tbody>
</table>
The 119 INDCs submitted as of October 1\textsuperscript{st}, 2015 were evaluated. As of October 1\textsuperscript{st}, 2015, 119 INDCs had been submitted, and representing about 88 per cent of global emissions in 2010.

Comprehensive evaluations of emission reduction efforts were only for 20 countries due to the limited regional resolution of the model.

Note: More ambitious emission reduction targets had been submitted as “conditional“ targets from some countries, but they are not considered in this evaluation.
International comparison of emission reduction ratios from the base year of 2005

It is not easy to measure ‘emission reduction efforts’ by using the emission reduction ratios from a certain base year due to large differences in future economic growth and historical achievements of energy saving improvements and emission reductions, for example.

* The average values are shown for the countries submitted the INDC with the upper and lower ranges.

**GHG emission compared to base year (2005) (%)**
International comparison of GHG emissions per GDP

GHG emission per GDP indicates economic efficiency of GHG emission in general, but it depends on the industrial structures and low-carbon energy supply potentials.

* The average values are shown for the countries submitted the INDC with the upper and lower ranges.
Large differences in marginal abatement costs are estimated across countries. The large differences raise concern about inducing the carbon leakage and the ineffectiveness of global emission reductions.
Since marginal abatement costs show the additional effort to be made, the retail prices of energy are also important indicators for measuring the total efforts including baseline's.
Many indicators (excepting emission reduction costs per GDP) of Switzerland, Japan, and EU were ranked high. CO2 marginal abatement cost of Australia is not high, but the emission reduction cost per GDP is large. On the other hand, some countries having poor rankings in many of the indicators are also observed.
- The marginal abatement costs widely across models for some countries, but can be comparable for many countries/regions.
- The CO₂ marginal abatement costs of the INDCs of OECD countries are much higher than the marginal cost for the case that the total reductions are achieved most cost-efficiently (globally uniform marginal abatement cost).

- The expected global GHG emission in 2030 is about 59.5 GtCO2eq. when all the submitted INDCs are successfully achieved. Emissions reductions from the baseline are estimated to be about 6.4 GtCO2eq, in which about 0.5 GtCO2eq reductions are offset due to carbon leakages from nations with INDCs of high marginal abatement costs to those with zero or low costs through induced lower fossil fuel prices.
- The expected temperature change in 2100 is +2 to +3 °C from preindustrial levels. The range depends on the uncertainties of climate sensitivity, and on future deep emission reductions through developments and deployments of innovative technologies.
Emission reduction costs rise by INDCs

- Comparison between the achievement by each country/region and the global least cost

- Due to large differences in marginal abatement costs across countries, we observe on the one hand severe economic impacts for some countries with high marginal abatement costs for the INDCs, and on the other hand positive impacts for countries with zero or low marginal abatement costs.

- In reality, achieving the INDCs could require much higher costs per country than the global least-cost emission reduction as the IPCC scenarios show.
Conclusions

♦ How to measure the ‘emission reduction efforts (degree of ambition)’ of INDCs is hard work but can be approached by employing multiple good indicators. Measuring the efforts is important for inducing effective emission reductions of the submitted INDCs and deeper emission reductions through a PDCA (Plan-Do-Check-Act) cycle.

♦ According to the evaluations on the submitted INDCs, marginal abatement costs were evaluated as zero for several nations such as China and India, meaning their INDCs are to be realized in BAU. Large differences in marginal abatement costs across nations induce carbon leakage and the less effectiveness of global emission reduction.

♦ Global emissions will be 60 GtCO₂eq in 2030 if all the nations realize their submitted INDCs. (Current emissions are 52–53GtCO₂eq) The 2030 emissions are considered to stay on the pathways of 2–3 °C temperature rise in 2100 relative to the pre-industrial level.

♦ Global emission reductions are estimated to become smaller than the simple sum of all the INDCs due to the carbon leakage effect that is caused when marginal abatement costs are substantially different across nations. All nations need to make equitable emission reduction efforts in order to effective global emission reductions.
